ABSTRACT: Communesins, isolated from the mycelium of a strain of *Penicillium* sp., are cytotoxic heptacyclic indole alkaloids bearing a bis-aminal structure and two contiguous quaternary carbon centers. Towards a total synthesis of communesin F, we synthesized a pentacyclic ABCDG ring skeleton via carboborylation of 1,3-diene and a Friedel-Crafts-type cyclization, resulting in the formation of an azepine ring through a $Bi(OTf)_3$-catalyzed S_N2' reaction.

Introduction

Communesins A and B, which were originally isolated by Numata and co-workers from the mycelium of a strain of *Penicillium* sp. attached to the marine alga *Enteromorpha intestinalis*, are heptacyclic indole alkaloids (Figure 1).[1] Spectroscopic analyses, including nuclear magnetic resonance (NMR) spectroscopy (^{1}H NMR, ^{13}C NMR including 2D NMR) and high-resolution mass spectrometry, have revealed that their structures are quite unique. They are characterized by a heptacyclic skeleton bearing two aminals and two contiguous quaternary carbon centers. To date, nine congeners have been reported,[2–6] and perophoramidine is also known as a structurally related bis-amidine indole alkaloid.[7] Recently, Tang and co-workers confirmed that communesins can be biosynthetically produced through the coupling of aurantioclavine and tryptamine based on genetic inactivation studies.[8] Communesins show cytotoxicity against P388 lymphocytic leukemia cells (ED_{50} A: 3.5 μg/mL, B: 0.45 μg/mL) and potent insecticidal activity towards silkworms (LD_{50} D: 300 μg/g, E: 80 μg/g). Because of their unique structure and biological activity, many research groups have conducted synthetic studies of communesins in which various synthetic methods were developed.[9–14] The first racemic total synthesis of communesin F was achieved by Qin and co-workers based on an intramolecular cyclopropanation strategy.[15] Weinreb and Funk also reported total synthesis of communesin F, independently.[16,17] The first asymmetric total syntheses of communesins A, B and F were accomplished by Ma and co-workers.[18,19] Asymmetric total syntheses were also reported by Stoltz, Movassaghi, Yang, and Chen, independently.[20–23] We have also engaged in the development of synthetic strategies for this class of alkaloids including communesins, perophoramidine and aurantioclavin.[24–31]

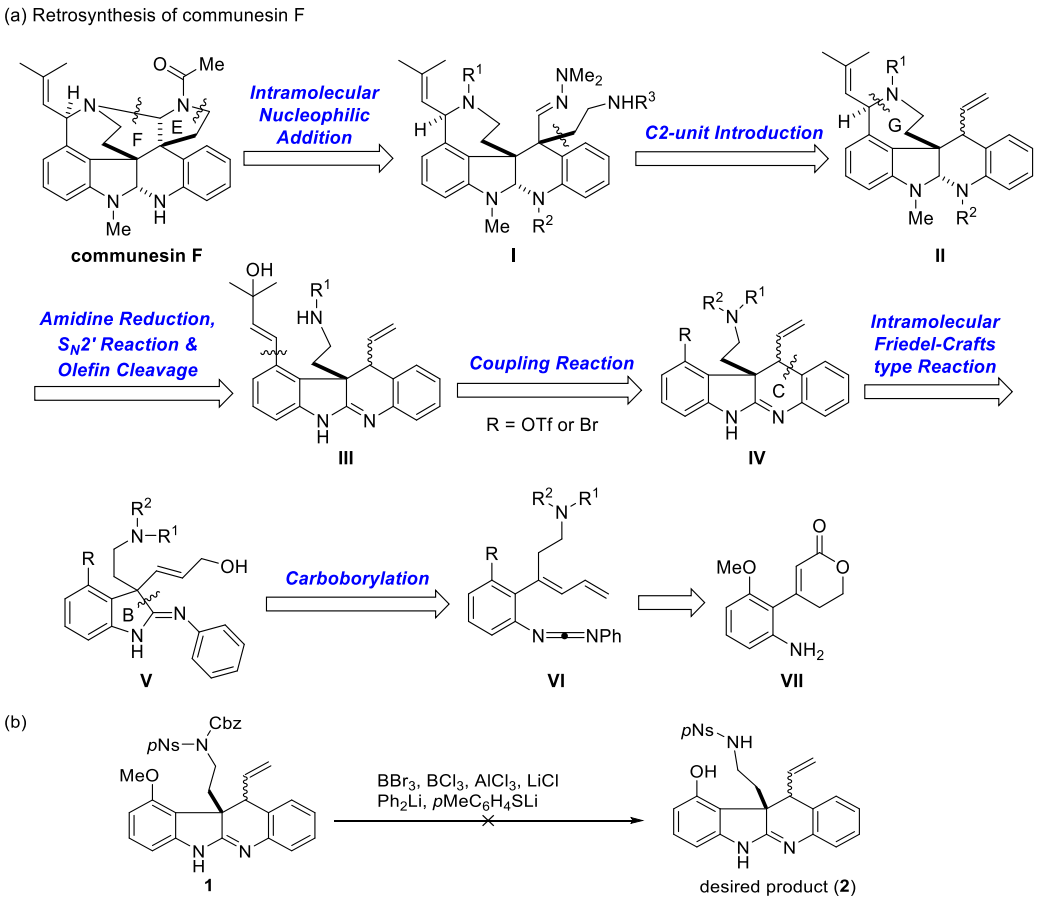
Results and Discussion

Recently, we have developed palladium(Pd)-catalyzed carbosilylation of 1,3-diene with carbamoyl chloride for the synthesis of several spirooxindoles.[32] Extending this reaction, a Pd-catalyzed carboborylation of 1,3-diene was developed for a synthesis of iminoindoline.[30] Considering our developed method, it was envisioned that communesin F would be accessed from a pentacyclic skeleton **II** through intermediate **I** by the introduction of an aminoethyl unit and the formation of amidine. The pentacyclic skeleton **II** would be constructed from a tetracyclic compound **IV** via **III** by the introduction of an allyl alcohol unit, resulting in an S_N2' reaction for the formation of an azepine ring and a reduction of amidine. The tetracyclic compound **IV** can be synthesized by a carboborylation of 1,3-diene **VI** and an intramolecular Friedel-Crafts-type reaction of a resultant iminoindoline **V**.[30] Following this retrosynthetic analysis, we have recently succeeded in the construction of tetracyclic skeleton **IV** (R = OMe) from diene **VI** (R = OMe) through iminoindoline **V** (R = OMe). However, compound **1** could not be converted to compound **2** through removal of the methyl group, although we tried various conditions including BBr_3, BCl_3, $AlCl_3$, LiCl, Ph_2PLi and *p*MeC_6H_4SLi (Scheme 1b).[33] These reaction conditions resulted in the removal of a Cbz group or the decomposition of compound **1**. Therefore, we needed to revise our initial synthetic route and planned to employ a 1,3-diene-containing triflate (R = OTf) to avoid a protecting group manipulation. The use of a substrate bearing a triflate group for Pd-catalyzed carboborylation would extend its reaction scope, and it might react itself under the reaction conditions. In the current manuscript, we report the construction of a pentacyclic skeleton of communesin F by extending our strategy based on carboborylation of 1,3-diene.



Scheme 1. (a) Retrosynthesis of communesin F and (b) failed attempt at removing a methyl group from compound **1**.

The synthesis started with a removal of a methyl group on a phenolic hydroxyl group. A methoxy aniline derivative **3**, which was prepared from *t*-butyl(3-methoxyphenyl)carbamate in four steps,[30] was treated using BBr_3 to give a phenol (Scheme 2). The resultant phenolic hydroxy group was silylated with *tert*-butyldimethylsilyl (TBS) chloride and imidazole to give compound **4**. A half reduction of a lactone with diisobutylaluminum hydride (DIBAL-H) was followed by Wittig olefination, which gave diene **5** through internal transfer of a TBS group. After the formation of urea by a treatment of phenyl isocyanate, a phenolic hydroxy group was protected as a triflate. A removal of a TBS group was followed by a Mitsunobu reaction with *p*NsNHBoc[34] to give compound **8**, which was converted to carbodiimide **9** through dehydration with CBr_4, PPh_3 and Et_3N.

With carbodiimide **9** containing a diene moiety, we investigated whether the triflate is intact under the reaction conditions of Pd-catalyzed carboborylation of 1,3-diene. In the previous literature, there is no report concerning

Pd(II)-catalyzed Miyaura borylation of triflates and diborone without a ligand, but reactions using diphenylphosphinoferrocene[35] or the reaction of arylbromide have been reported.[36] Therefore, it was expected that a triflate group would be intact during the carboborylation of 1,3-diene. As expected, the reaction of **9** proceeded smoothly under the established conditions ($Pd(OAc)_2$, $(pinB)_2$, xylene, 50°C) to give an allyl borane, which was treated with $NaBO_3 \cdot 4H_2O$ to give allyl alcohol **10**. After silylation of allyl alcohol **10**, a *tert*-butoxyoxycarbonyl (Boc) group was introduced to an amidine nitrogen for further transformation. The treatment of compound **11** using tetrabutylammonium fluoride gave an allyl alcohol along with the removal of a triflate group, which was converted to allyl bromide **12** under standard conditions. Unfortunately, the resultant allyl bromide **12** could not be converted to compound **13** through a treatment of Tf_2O and pyridine. On the other hand, when HF·pyridine was used, a triethylsilyl group was selectively removed with the triflate group intact. The resultant allyl alcohol was also converted to allyl bromide **13** containing a triflate group, while a small amount of compound **14** was also obtained through the removal of a Boc group.

and its derivatization.

Next, we investigated Friedel-Crafts-type cyclization of allyl bromides **12** and **13** to construct a tetracyclic ABCD ring skeleton. Previously, we have reported the cyclization of compound **15** containing a methoxy group using 10 mol% of $Bi(OTf)_3$ and 3.5 equivalents of AgOTf (Table 1, entry 1).[30,37–39] The reaction gave compound **16a** in 49% yield along with **16b** in 30% yield. We initially applied these conditions to a cyclization of compound **13** containing a triflate group. However, the reaction gave a complex mixture instead of any cyclized products **17a** and **17b** (entry 2). On the other hand, the cyclization of compound **12** containing a phenolic hydroxy group proceeded under the same conditions to give compounds **18a** and **18b** in 63% and 30% yields with excellent stereochemistry, respectively (entry 3). The stereochemistry was determined by a comparison with our previous results[30] and a NOESY experiment of a derivatized compound **28** (Scheme 4, *vide infra*). When 3.5 equivalents of AgOTf was reduced to 1.2 equivalents, the formation of byproduct **18b** was suppressed to 17% yield (entry 4). Finally, the yield of the desired product **18a** was improved to 80% yield using 1.05 equivalents of AgOTf (entry 5). AgOTf was essential for this Friedel-Crafts-type reaction (entry 6)

Table 1. Formation of a tetracyclic ABCD skeleton through a Friedel-Crafts-type reaction.

After the construction of a tetracyclic ABCD ring skeleton containing an amidine, we turned our attention to the

formation of an azepine ring (G ring). A treatment of compound **18a** with Tf_2O and pyridine gave compound **17a** in 91% yield (Scheme 3). To introduce an allyl alcohol unit, Suzuki-Miyaura coupling with vinyl boronic ester **19** was examined. When compound **17a** and vinyl boronic ester **19** were treated with a catalytic amount of $Pd(dba)_2$, SPhos and K_3PO_4, or $Pd(PPh_3)_4$ and Na_2CO_3 in *N*,*N*-dimethylformamide (DMF) at 100°C, respectively, these reactions gave the desired product **20** in low yields (Table 2, entries 1 and 2). However, conditions involving $Pd(PPh_3)_4$ and Na_2CO_3 in toluene and ethanol at 100°C improved the yield to 56% (entry 3). The removal of the *p*Ns and trimethylsilyl (TMS) group gave allyl alcohol **21** in 66% yield over two steps. To construct the azepine ring, mesylation of a tertiary alcohol was initially attempted through a treatment using methanesulfonyl chloride (MsCl) and Et_3N.[18] However, a dehydration occurred to give diene **23** instead of the desired cyclized product **22**. Interestingly, when compound **21** was treated with pyridinium *p*-toluenesulfonate (PPTS),[15] ortho-amide **24** was observed (as assessed using ^1H NMR analysis). A related structure was observed in synthetic studies of dehaloperophoramidine reported by Somfai and co-workers.[13,14] We considered the thermodynamic stability of possible equilibrium products such as simplified compounds **25**, **26** and **27** through density functional theory (DFT) calculations (Figure 2). These calculations revealed that ortho-amide **26** was the most stable isomer among these compounds. These results indicate that the formation of the ortho-amide through acid activation using PPTS from amidine would be a competitive process with the formation of the azepine ring via the S_N2 reaction of the tertiary alcohol, and the equilibrium tends to be biased towards the ortho-amides such as compounds **24** and **26**. Therefore, we expected that it would be difficult to achieve the formation of azepine **22** from compound **21** containing the amidine moiety.

Therefore, a reduction of amidine **20** was investigated prior to the formation of the azepine ring to avoid the formation of the ortho-amide (Scheme 4). When compound **20** was treated using $NaBH_4$, the desired product was not obtained. In the case of DIBAL-H, the removal of a Boc group occurred instead of the reduction of the amidine. However, in sharp contrast, treatment using catecholborane[40] gave the desired product **28** in 65% yield as a 3.3:1 mixture of diastereomers. A NOESY experiment indicated that the stereochemistry of the major isomer was a *trans*-fused structure, which would be epimerized to a *cis*-fused structure later. Because a reducing reagent approached from the less hindered face, the *trans* isomer was obtained as a major product in this reaction. After the removal of Boc and the TMS groups, the formation of an azepine ring was investigated again. When compound **29** was treated using MsCl and Et_3N,[18] the reaction gave diene **31** in 48% yield and the desired cyclized product **30** was not detected at all (Table 3, entry 1). When $Bi(OTf)_3$ was employed at −15°C as a Lewis acid, the reaction proceeded to give the desired product **30** as a major product albeit in low yield (entry 2).[41,42] The reaction using $Bi(OTf)_3$ at −40°C gave the desired product **30** in 17% yield with recovery of the starting material (entry 3). However, under room temperature reaction

conditions the starting material **29** was consumed completely to give the desired azepine **30** in 55% yield, while diene **31** was obtained in 34% yield (entry 4). The obtained pentacyclic compound **30** would be useful for further derivatization, and now we are investigating further transformations to achieve a total synthesis of communesin F.

In summary, we have investigated the synthesis of a pentacyclic ABCDG ring skeleton of communesin F based on carboborylation of 1,3-diene, a $Bi(OTf)_3$-catalyzed Friedel-Crafts-type reaction and azepine ring formation. It is interesting that a triflate group was intact under the conditions required for Pd-catalyzed carboborylation of 1,3-diene. Additionally, it was essential that the resultant amidine was reduced prior to the formation of the azepine ring through $Bi(OTf)_3$-catalyzed cyclization to avoid an undesired formation of ortho-amide. We are currently investigating further transformation of the pentacyclic compound to complete the synthesis of communesin F.

Experimental Procedure

General. All non-aqueous reactions were carried out under a positive pressure of argon in over-dried glassware. Analytical thin-layer chromatography was performed using Silica gel 60 plates (Merck, Darmstadt, Germany). Silica gel column chromatography was performed using Kanto silica gel 60 (particle size 63–210 μm, Kanto, Tokyo, Japan) and Chromatorex BW-300 (Fuji silysia, Aichi, Japan). Proton nuclear magnetic resonance (^{1}H NMR) spectra were recorded using a JNM-ECA 500 (JEOL, Tokyo, Japan) at 500 MHz or a JNM-AL 400 (JEOL) at 400 MHz. Chemical shifts were reported relative to Me_4Si (δ 0.00) in $CDCl_3$ or the residual solvent peak in C_6D_6 (δ 7.16). Multiplicity was indicated by one or more of the following: s (singlet); d (doublet); t (triplet); q (quartet); m (multiplet); br (broad). Carbon nuclear magnetic resonance (^{13}C NMR) spectra were recorded using a JNM-ECA 500 at 126 MHz or a JNM-AL 400 at 100 MHz. Chemical shifts were reported relative to $CDCl_3$ (δ 77.0) or C_6D_6 (δ 128.0). Infrared spectra were recorded using a FT/IR-4100 Fourier-transform infrared spectrometer (JASCO, Tokyo, Japan) with ATR (attenuated total reflectance). Low and high resolution mass spectra were recorded using a JMS-700 mass spectrometer (JEOL) for FAB-MS and a LCMS-IT-TOF (Shimadzu, Kyoto, Japan) for ESI-MS.
